

Adoption of an information systems security policy in small and medium sized enterprises

Isabel Maria Lopes^{1*} & Pedro Oliveira¹
¹*Polytechnic of Bragança, PORTUGAL*

ABSTRACT

Information Systems Security (ISS) is a relevant fact for current organizations. This paper focuses on Small and Medium Sized Enterprises (SMEs). This article aims to constitute an empirical study on the applicability of the Action Research (AR) method in information systems, more specifically by assessing the adoption of an ISS policy in six SMEs, and identifying the critical success factors in adopting an ISS policy. The research question we intend to answer is to what extent this research method is adequate to reach the proposed goal. The results of the study suggest that AR is a promising means for the evaluation of ISS policies adoption. It can both act as a research method that improves the understanding about the reasons why the policy has been abandoned, and as a change method, assisting practitioners to overcome barriers and suggesting measures to be implemented.

INTRODUCTION

Information Systems Security is a crucial issue for most organizations. With the advent of information technology and the massive use of the Internet and its services, the number of attacks to which information is subject is increasingly higher and, consequently, the need to protect information systems is becoming imperious.

Security policies have a central role in ISS literature, appearing as one of the crucial factors to the information security of an organization.

The CIA triad – Confidentiality, Integrity and Availability – represents the conventional properties which guide the analysis, planning and implementation of information security. Other properties such as legitimacy and authenticity are emerging because of the widespread of the use of commercial transactions through computer networks worldwide (Dhillon et al., 2000).

The classic principles of CIA can be explained as follows:

- Confidentiality – access to information restricted to legitimate entities, that is to say those authorized by the information owner.
- Integrity – manipulated information must preserve all the original features established by the information owner, ensuring that the content is not altered without permission.
- Availability – the information is available for legitimate use at all times, whenever necessary.

One of the means which can be used to ensure information integrity, availability and confidentiality within an organization is ISS policies.

Structurally, this paper is organized as follows. After this contextualization of the topic under study, we briefly present what is understood by the adoption of an ISS policy, and we review the main tenets and characteristics of AR in general. Thereafter, we describe the way in which the AR steps were applied towards

*Correspondence to: isalopes@ipb.pt

the adoption of an ISS policy by the companies. The discussion of results presents a set of critical success points that ensure a successful adoption of an ISS policy. Finally, we enumerate the papers' main contribution, limitations, and suggestions for future works.

ADOPTION OF INFORMATION SYSTEMS SECURITY POLICIES

The increasing dependence of organizations in general and SMEs in particular on their information systems has led to a higher value of information, which has assumed a vital relevance to organizations. In the past, the main focus of organizations lied essentially on their tangible assets (physical and financial). However, over the last years, this reality has been altered and nowadays, organizations have included in their main focus another asset – information.

Information systems security is a critical issue to be taken into account within organizations worldwide, regardless of their size or location. Due to the growing number of threats to which information is submitted, the need to protect information systems reveals to be increasingly more pertinent and imperative.

There are several measures which can and must be implemented within SMEs in order to ensure the effective functioning of ISS. According to (Höne et al.,2002:402), “these measures include technical solutions and contractual regulations as well as organizational warnings regarding common risks, threats and vulnerabilities. Undoubtedly, the most important singularity of these provisions is the information security policy.”

Nowadays, the adoption of measures such as the implementation of an ISS policy which may contribute for preserving information confidentiality, integrity and availability represents a demand within any organization. These are “documents which guide or regulate people or systems' actions in the domain of information systems security” (de Sá-Soares, 2005:56). Another author, (Gilbert, 2003:3), defines policy as “the rules and procedures chosen to dictate future actions.”

The importance of ISS Policies is stressed by several authors, such as (Peltier, 2002:21), who classifies them as the “cornerstone of an effective information security architecture”. According to (Kee, 2001:1), security policies are “the Foundation and the base line of information security within an organization.”

In order to implement an ISS policy, an organization must follow a sequence of steps, starting by writing the policy, then implementing it, and later on, at predefined moments or whenever circumstances require it, by reviewing its provisions, which may prompt modifications in the policy. Indeed, this sequence of steps may be viewed as a cycle of formulation – implementation – revision – adoption of the policy.

According to (Hartley et al., 2001), the development of a security policy within an organization involves four activities:

- Assessing and understanding the security needs;
- Reviewing the policies and procedures in use, if they happen to exist;
- Defining the protection requirements;
- Formalizing the security policy.

The first two points are essentially meant to collect information and require a combination of security technical knowledge and risk management analytic knowledge. The third point is purely analytic and therefore, demands analytic and technical knowledge as well as a reasonable understanding of risk management principles. The fourth activity has a more administrative nature, as it consists of drafting the final document which formalizes the organization's security policy.

When focusing our attention on a specific type of organization – SMEs – a study carried out by (Lopes et al., 2014) revealed that among the 307 SMEs surveyed, only 15 stated to have an ISS policy. One of the conclusions drawn from that study was that the implementation and consequent adoption of an ISS policy has not become a reality in SMEs yet.

This paper aims to constitute an empirical study on the applicability of the AR method in the field of Information, more specifically analyzing the adoption of ISS policies in SMEs and identifying the critical success factors in adopting an ISS policy. Hence, the research question that guided this work was to what extent AR methodology is adequate to support the process leading to the adoption of ISS policies.

PERSPECTIVES ON ACTION RESEARCH

Given the aim proposed for this study as well as the philosophical framework guiding the researchers, the research method chosen for the present study was “Action Research”. Hereafter, we briefly define this research method as well as its characteristics and applicability within the field of ISS policies.

AR considers the iterative process of interaction and focus on a research problem. Therefore, the first step to trigger it is identifying the problem and formulating it into a goal and in a way that it can be operated. The intervention aspect of AR means that it is an especially interesting and relevant method for the area of information systems development (Avison et al., 1998).

AR can be described as a family of research methodologies which pursue action (or change) and research (or understanding) at the same time. It is characterized by the cyclic revision of action followed by reflection, often culminating in the refinement of understanding using methods such as modelling. The iterative nature of the methodology promotes convergence to a greater understanding (Dick, 1999).

Williams, 2006 described AR as similar to the case study approach in describing the richness of an environment, and as similar to field experimentation in working in situ, but adding to these features intervention and reflection. The strengths of the AR method lie on its iterative cycle within a real-world context of assessment, action and reflection, with potential participant input and practical and applicable outcomes.

According to (Cohen, 1994), AR is essentially an in loco procedure which views to tackle a concrete problem located within an immediate situation. The process is controlled step by step during varying periods of time, through diverse data collection techniques (questionnaire, interviews, etc.) and the subsequent results must enable the introduction of changes, adjustments, direction changes and redefinitions according to needs, which may bring long-lasting advantages to the on-course process itself.

Although different authors may have diverse perspectives concerning the usefulness of the AR method, there seem to be broad consensus regarding the method’s general architecture. In short, the AR method starts with the detection of a problem, from which some changes are projected aiming to solve the problem. This process is cyclic as when applied to organizations or other social groups, it is unlikely that a problem is considered permanently solved and will rather suffer alterations and require new intervention. Thus, AR constitutes a methodological approach directed towards change: it is not limited to the understanding of phenomena but it also deliberately aims to change those phenomena.

AR modalities

Similarly to what happens with other research methods, AR can be developed in several ways. Such diversity may depend on the contexts within which it is applied, the people involved, or the conditions within which it is developed. According to (Coutinho et al., 2009), the main modalities are as follows (Figure 1): technical, practical, and critical or emancipatory. These modalities approach different aspects such as: goals, the researcher’s role, the kind of knowledge it generates, the ways of action, and the participation level.

The technical modality can be used as primary research learning and only aims to obtain pre-established results.

The practical modality helps to develop the stakeholders’ reasoning and practical judgment. The researcher assumes a Socratic role, therefore not interfering in the process or questioning its course.

In the critical or emancipatory modality, both the internal and external stakeholders collectively take responsibility in the development and practice transformation. The external stakeholder must temporarily take the role of a moderator, helping to problematize and modify practices as well as to identify and develop

Technical Modality	Practical Modality	Critical Modality
<p>Goal – Improve actions and the system’s efficiency</p> <p>Researcher’s role – External expert</p> <p>Kind of knowledge generated – Technical, Explanatory</p> <p>Ways of action – On the action</p> <p>Participation level – Co-option</p>	<p>Goal – Understand reality</p> <p>Researcher’s role – Socratic role (favor participation and self-reflection)</p> <p>Kind of knowledge generated – Practical</p> <p>Ways of action – For the action</p> <p>Participation level – Cooperation</p>	<p>Goal – Participate in social transformation</p> <p>Researcher’s role – Process moderator</p> <p>Kind of knowledge generated – Emancipatory</p> <p>Ways of action – Through action</p> <p>Participation level – Collaboration</p>

Figure 1. AR modalities

their self-understanding. Responsibilities regarding change are taken jointly.

An approach is suggested by (Lau, 1997), who presents a taxonomy of four classes: Action Research, Participatory Action Research, Action Science, and Action Learning. Lau uses this systematization to analyze three decades of significant papers on Action Research within the field of information systems. The four classes presented by the author are distinct in the following aspects:

- Action Research – Technique characterized by living and experiencing the intervention, operating on problems or issues perceived by the participants within a particular context.
- Participatory Action Research – It differs from the former because it involves an additional involvement by its participants as subjects and researchers.
- Action Science – It places special emphasis on the theories-in-use which participants reveal through practice and research.
- Action Learning – It is characterized by its goal to change the way of learning and the framework through action, thus enabling an effective learning and transformation.

AR execution cycle

What best characterizes and identifies AR is the fact that it is a research methodology essentially practical and applied which is ruled by the need to solve real problems. Along with the research, there is an action which aims to transform reality and subsequently, produce knowledge of the transformations resulting from the action (Hugon et al., 1988).

AR is ruled by the need to solve real problems and assumes some essential characteristics pointed out by authors such as (Dick, 2000), (Descombe,1999) and (Cohen et al., 1994):

- Participatory and collaborative – as all the participants are involved in the process. They all are co-actors of the research. The practitioner is not an external agent who does research with people, but a co-researcher with and for those who are interested in practical problems and in improving situations.
- Practical and interventional – it is not limited to the theoretical field of describing a certain reality. Action must be linked to change and is always deliberate.
- Cyclic – The research involves a spiral of cycles in which the initial findings generate possibilities of change, which are implemented and assessed as an introduction to the following cycle. The cycle varies according to the author, but it includes at least the following stages: Planning – Action – Reflection.
- Critical – The critical community of participants are not only looking for better practices concerning their work, within certain sociopolitical restrictions, but they also act as agents of change, critics and self-critics regarding possible restrictions. They change their environment and are transformed in the process.
- Self-assessing – Changes are continuously assessed within a perspective of adaptability and production of new knowledge.
- Qualitative – it is predominantly qualitative although some situations may require some quantification.

According to (Pring, 2000) some of the key features of Action Research are:

- Cyclic and recursive. Similar situations tend to repeat themselves in similar ways.
- Participatory. The participants in the research process have bonds of cooption, cooperation and collaboration.
- Qualitative. It deals more with ideas than with figures.
- Reflexive. Critical reflection on the process and its results is an important stage of each cycle.

AR is characterized by a set of stages whose sequence enables the implementation of the method within a certain context and the solving of a certain problem. Different authors present different stages. Among such a wide variety of models, we selected four, as we consider this number to be sufficient to illustrate their scope and differences.

Cunha et al., 2002 present a model adapted from Dick (1992) which includes three steps: Planning; Action; and Reflection, as presented in Figure 2.

Based on these three building blocks, (Cunha et al., 2002) summarize the philosophy underlying AR: “You plan an intervention (Planning); you execute the corresponding action (Action), thus inducing a change which will hopefully lead to some development; finally, you do a critical analysis of the results, which supposedly

leads to a better knowledge of the situation. This, in turn, enables you to make adjustments leading to new cycles (Reflection).”

These three stages of AR assume the outlining presented in Figure 3.

According to (Kember, 2000) and (Zuber-Skerritt, 1996), the AR cyclic process or spiral comprises four different stages, namely planning; action; observation; and reflection. For this author, it is normal for an AR project to go through two or more iterative cycles. The product resulting from each cycle improves as the cycles are repeated, and each of these cycles includes reflections on the previous ones.

Cohen et al., 1994, view the development of an AR project through the following steps:

- Identification, assessment and formulation of a problem;
- Preliminary discussion and negotiation between the parties involved;
- Review of literature regarding the field of research;
- Review of the initial problem formulation;
- Selection of research procedures;
- Selection of assessment procedures;
- Implementation of the project;
- Interpretation of the collected data.

Susman et al., 1978, view a general AR project as a cyclic process, which is referred to by them as the AR cycle. According to their view, the typical AR cycle is composed of five stages: diagnosing; action planning; action taking; evaluating; and specifying learning. Diagnosing is related to the identification and definition of a problem to be solved in the client’s organization. Action planning considers alternative courses of action to solve the problem. Action taking includes the selection and execution of a course of action. Evaluating comprises the study of the outcomes of the selected course of action. Specifying learning is the stage in which the study accomplished in the previous phases will be structured in the form of general findings (Figure 4).

Associated with each of the stages included in this model are the following goals:

- Diagnosing – Identification of a problematic situation, related to the need of change within a certain organization;
- Action Planning – Specification of the organizational actions which must be undertaken in order to solve the problems identified in the diagnostic;
- Action Taking – Implementation of the actions previously planned which will supposedly lead to changes;

Figure 2. Three steps AR cycle

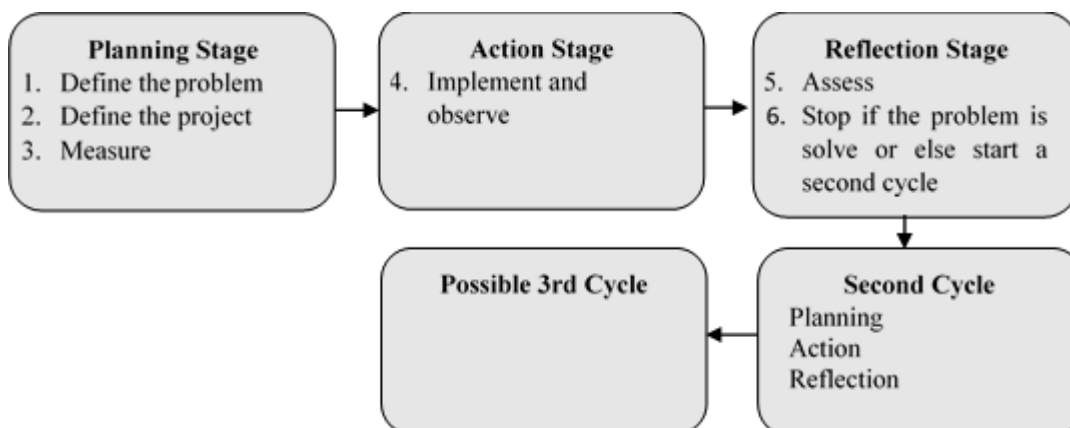

Figure 3. AR stages

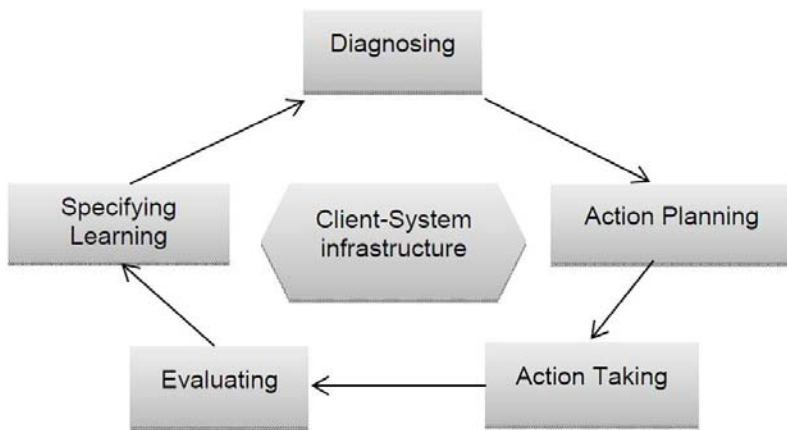

Figure 4. Five steps AR cycle

- Evaluating – Assessment of the intended goals achievement and solution;
- Specifying Learning – Specification of the knowledge acquired with the introduced change. Although this stage appears as the last one in the scheme, it represents a permanent process.

Rigor and validity supports

According to (Cunha et al., 2001:1), scientific research in some areas of IS involves challenges which prevent the use of approaches widely established and applied to other situations. “It is the case of new development technologies, where the strong socio-organizational implications collide with the techniques usually used to ensure the rigor of the process as well as the validity of the results obtained.”

The rigor of the research process and the validity of the results obtained are frequently associated with the problem decomposition, the research procedures standardization and the collection of rigorous quantitative measures, obtained through experiments thoroughly controlled by independent researchers. Several authors cited by (Cunha et al., 2001) have focused on the issue related to finding approaches that would be capable of responding to the previously listed challenges, and have pointed out AR as the adequate alternative.

In order to ensure rigor in the AR process, ensuring the quality of the findings so that subsequent assertions are considered valid, a set of tactics are suggested by various authors such as (Baskerville, 1999; Baskerville et al, 1996; Checkland et al., 1998; Dick, 1997; Dick, 1999a; Dick, 1999b; Dick et al., 1994; Lau, 1999). Therefore, a brief overview of such tactics is presented below (Cunha et al., 2001):

- There must be, from the beginning, a theoretical framework that will constitute the reference to define what represents new knowledge arisen throughout the process. This requirement is uncompromisingly referred to as fundamental by (Checkland et al., 1998), and has had increasing acceptance by other authors (Lau, 1999);
- The use of cycles must be promoted. In each of them, the researcher must try to refute the emerging interpretation. The use of several cycles provides more opportunities for that. Cascaded processes with different lengths may eventually be used;
- Within each cycle, both the methods used and the questions under analysis can be criticized and refined;
- Data collection and interpretation can be concluded within each cycle. Thus, both can be tested in following cycles;
- In each cycle, the researcher must focus only on concordant and discordant information (ignoring idiosyncratic information). Apparent concordances must be tested, whereas apparent discordances must be explained;
- Divergent data can be searched intentionally, thus increasing the possibilities of data confrontation or updated interpretations with new data. Literature itself can be used as a source within this process;
- In each cycle, the researcher can try multiple sources of information (or else different perspectives on the same source) so as to build a dialectics. For this, different data collection methods, interlocutors and researchers can be used, as well as redundant data obtained from the same interlocutor, among other mechanisms;

- The changes proposed as a result of the work derive both from the data and from its interpretation, thus representing one more opportunity for refutation.

ACTION RESEARCH APPLIED TO THE ADOPTION OF INFORMATION SYSTEMS SECURITY POLICIES

Action Research was primarily applied in the academic milieu of Social and Medical Sciences, but in 1990, it started to be successfully explored in the areas of Educational Sciences, organizations learning and Information Systems (Baskerville, 1996).

One of the main reasons pointed out to justify the use of qualitative research methods in the field of IS is the fact that Information Systems include the human element as a variable or as a determining research factor, whether the study focuses on the individual or on the group, as in the case of organizations or companies (Silva, 2002).

Thus, AR constitutes “one of the few research approaches which we can legitimately use to study the effects of specific changes in methods of systems development within human organizations.” (Baskerville et al., 1996).

For these reasons, we consider that the application of the AR research method is adequate to study the adoption of ISS policies by SMEs.

The creation of an ISS policy follows a complete life cycle from its formulation to its adoption, including its implementation and review. This study mainly focuses on the stage of adoption of an ISS policy. Therefore, before presenting the results of the study, we will briefly present what is understood by the adoption of an ISS policy.

Due to the nature of the diverse organizations where different and distinct users access and use the information system, the adoption and concomitant compliance with ISS policies is essential to enable the detection of flaws and incoherencies in the adoption process and to lead to their correction.

According to (Karyda et al., 2005), the adoption of a policy includes elements of input, which feed certain procedures of activities, which in turn originate a set of outputs. Figure 5 represent a scheme illustrating these authors’ view.

Input	Activities	Output
<ul style="list-style-type: none"> • Evaluation of the use of the Security Policy • Established security procedures and work practices that implement the security policy • Education and training programs 	<ul style="list-style-type: none"> • Establish norms that support security management • Promote the issue of security to IS users • Resolve possible conflicts and difficulties in the application of the security controls • Keep users and management informed on the IS security agenda 	<ul style="list-style-type: none"> • Security culture • Proposals and requirements for improving and adjusting the security policy

Figure 5. The process of security policy adoption

Within the process of adoption of an ISS policy, inputs include the evaluation of the policy during its implementation, the procedures and working practices which implement the security policy, and the users’ training and education processes. Based on this information, the following process includes solving possible conflicts and difficulties detected in the application of certain parameters contained in the policy, and keep users and managers informed on the ISS agenda.

This process of adoption of a policy is coincident with the AR cyclic model mentioned in point 3 of this study in many respects. Therefore, this study was structured according to the model proposed by (Susman et al., 1978), which is composed of five steps: Diagnosing; Action planning; Action taking; Evaluation and Specifying learning (Figure 4).

As it has been mentioned above, the AR cycle starts with the detection of a problem. In this study, identifying the problem was a simple and unambiguous task. Such detection derived from acknowledging the study carried out by (Lopes et al., 2014), in which 307 SMEs heads of the IT department were inquired about the existence or not of an ISS policy in their company, and in which the results showed that only 15 of the companies stated to have an ISS policy in their organization.

Having identified the problem, the present study aimed to verify whether or not the ISS policy implemented in the organizations is truly adopted by them. In other words, the aim of this study is to detect the critical success factors in the adoption an ISS policy. In order to achieve this aim, we studied six SMEs and assessed in loco whether or not the ISS policies are respected and followed by users in the organization's day-to-day activity and what critical success factors impact on their adoption. The time spend in each SME was approximately one week, with periodic sectorial meetings.

In the first stage – Diagnosing – a problematic situation was identified, namely the non-institutionalization of an ISS policy by SMEs. Companies recognize the importance of a policy for the security of their assets, namely information. However, few are able to implement one and therefore, originate a context of change within the organization. Nevertheless, the main question to be answered is to what extent the policies which were implemented by the companies were actually adopted by those companies. On these grounds, conviction was reinforced that AR may reveal particularly adequate to change this situation.

The researcher was faced with the realities of the six SMEs, making a first contact with the company through the Head of the IT department, questioning them about whether or not the ISS policy previously implemented was being adopted. It was found that although all the interviewees wanted the policy to be adopted within the organization, such adoption was not taking place in 4 of the companies.

In two cases, the reason pointed out for the non-adoption was the users' lack of awareness towards the information security issue, thus not respecting the provisions established in the policy. In one case, the policy document revealed to be very long and confusing, which made its implementation difficult. In another company, the Head of the IT department took responsibility for the non-adoption of the policy, stating that he had failed to disseminate the policy among all users and had not taken the necessary actions for its implementation.

In the second stage – Action Planning – we specified the actions which had to be executed so that the ISS policy could be implemented. Those actions were formulated jointly by the researcher and the company's representative accompanying the process. The process started with a review of the document in the four SMEs. In three of them, some adjustments were made, and in one of the cases, the document was almost completely redrawn. After this, and before moving on to the implementation planning, we analyzed the factors which had previously failed so that similar mistakes would not be repeated.

Besides planning the actions to be executed in order to implement the policy itself, the Heads of the IT department in the six companies and the researcher jointly contributed with their experience to draw a set of critical success points to the adoption of the ISS policy.

In the third stage – Action – we implemented the actions previously defined, expecting that these would lead to a change within the organization. This step involved several phases, starting with the review of the policy document, moving on to its approval by the executive board and further on to its dissemination among all users.

The fourth stage, called – Evaluation – aims to assess whether or not the goals were achieved and the problems were solved. This evaluation requires the review of the ISS policy, which must take place within a well-defined time frame, or whenever significant changes are observed within the company for the policy to continue to play its role. In the six companies involved in this study, evaluation was carried out by checking users' compliance with the provisions established in the policy. As far as the review of the policy is concerned, we considered that it was not necessary yet.

The last stage – Learning – is usually listed at the end of the process. However, it is a permanent process since the learning occurring throughout the whole cycle can be used as a starting point for a new cycle whenever necessary.

DISCUSSION

AR is an emergent methodology as it provides flexibility, adequate answers and change. Its process is well adjusted to the demands of the situation in all its complexity. AR open attitude towards knowledge enables this method to provide a more effective change, which in turn, stimulates a more effective understanding of the problem.

By using this methodology, we tried to help SMEs change a concrete situation, which was the non-adoption of an ISS policy. Also, we tried to understand that specific situation and to alter it. The goal concerning the adoption of an ISS policy by the four SMEs was achieved by identifying and later on implementing the key-points to its adoption, or in other words, the factors considered as critical to the success of a policy.

We hereafter present a brief list of critical success factors to the adoption of an ISS policy, identifying the aspects pointed out as crucial by the members in charge for the six SMEs involved in this study.

The success of a policy highly depends on the adoption and compliance with the policy by its users. It is important to draw individual responsibilities, for instance, by clarifying who has access to each specific part of the system.

Another aspect which was considered as a critical success factor to a good implementation is the definition of sanctions for users who do not comply with the provisions of the policy.

Having the support of the organizations' managers in the formulation and adoption of the policies is also an essential critical factor to the success of an ISS policy. Only the involvement of all cooperators and mainly the involvement of managers and executives can grant a good formulation and adoption of the policy.

The periodic review of ISS policies is also crucial. A policy by itself will be of little use if it is not updated. Organizations are increasingly more dynamic and as a consequence, changes in structure or in the way they operate happen at a highly quick pace. Therefore, it is necessary to adapt the policy to those new realities.

The communication and dissemination of the policy among all those who must know it and comply with it have also been pointed out as being crucial to the success of the policies. It is easily understood that all users must acknowledge the existence of a security policy as well as its contents. Although the ways to disseminate the policy document may vary (internal memorandum, provision of the policy on the organization's intranet, or other mechanisms), it is necessary to ensure everybody's acknowledgment of the policy content.

Integrating the policy with the organization's goals, processes and culture is fundamental for the success of its implementation. An ISS policy must be a constructive and protective vehicle and never a mechanism which may hinder the good development of the organization's functioning. In order to achieve this, it is necessary that the creators of the policy take into account the company's goals as well as its organizational processes and culture before drawing the document.

The policies workability (regarding their implementation and compliance) represents another essential factor. Having an ISS policy will be by itself of little use if its workability reveals to be impossible.

It is necessary to raise awareness of the people involved towards the fact that technology is not the only element to take into account. Without an ISS policy, but also without methods of response to incidents or a business continuity plan, technologies will not be effective in the protection of the organization's information.

One more aspect to consider is related to both users and managers' awareness towards security issues. This aspect is particularly relevant as the human factor is pointed out as the main responsible for the majority of incidents regarding security. Therefore, awareness towards such issues is fundamental to enable the organizational ISS policy to produce the desired result (Lopes, 2012).

The ISS policy must include a set of guidelines, provisions and procedures which must be obeyed with a view to raising users' awareness and guiding them towards a secure use of technologies. Therefore, the policy must contain information on how to manage, save and protect one of the company's main assets – information.

CONCLUSION

The process of adopting an ISS policy involves a set of stages which include inputs and effective activities. The process developed in this study can also be considered as the effective process of the policy since the evaluation process started simultaneously with its implementation, resulting in a real awareness raising concerning the importance of the policy and the subsequent organizational culture as well as in feedback for possible adjustments of the policy.

It was possible to conduct these stages, which involve a dynamic of action – reflection – action, by using the AR methodology, which proved to be effective to the adoption of an ISS policy in the four SMEs taking part in the study. This research work involved six SMEs, two of which had already adopted a policy, thus enabling the collection of distinct data, namely the key-points to a well-succeeded adoption. In the remaining four SMEs, the work which was carried out required a bigger proximity in order to rectify the problem identified, which consisted of the non-adoption of the ISS policy in the day-to-day operations of the organization.

This research work presents limitations, namely with respect to the number of SMEs involved. Although we believe that the study carried out in the six SMEs generated enough data to serve the goal of the study, we also believe that a larger number might result in a more sustained set of data. Nevertheless, we highlight that

the application of the AR method requires the researcher's direct involvement, thus requiring a substantial amount of time.

Throughout this study, some guidelines were identified regarding the development of future works. Consequently, we found two promising starting points for further studies. The first point consists of a proposal of an ISS policy model that can be followed by SMEs in order to facilitate their formulation and further implementation of a policy on their own. The second point is based on the premise that the issue of information security is common to different organisms. Therefore, comparing different policies from diverse organizations may represent a good proposal of research.
